In this tutorial, we will discuss how to install an Apache Tomcat server on a VMware Virtual Machine (VM) using the command line. We will also go through the various steps related to the installation of a Tomcat server on a CentOS 6 server using the command line. This will be a Linux CentOS 6.3 tutorial, which should be easy enough to follow along. We have prepared everything for you to try this tutorial by setting up the VM on VMware Fusion and installing Tomcat within the VM. You can choose to install Tomcat as a web server or not. I have used this tutorial to install Tomcat on a CentOS 6 VM on my Mac as a local web server (by choosing "No" for installing Tomcat as a web server). If you want to set up a web server to host your own website, it is probably a good idea to do that as we will cover it in another tutorial. Since you have to run this on a VM, it would be easier to write the commands in a notepad document. If you have any issues or something is unclear, please let us know by commenting below. Once again, the download link to the VMware ESXi installer is [here](#). I assume you have VMware Fusion and the latest version of it installed. Step 1: Download the VMware ESXi Installer Install a VM on VMware Fusion While VMware provides you with preinstalled VMs, sometimes you need to make changes to the installed ones and install a new VM. In order to install a new VM on VMware Fusion, you need to launch VMware Fusion, go to Preferences, then to Install a New VM. Once you have your Mac ready, launch the VMware Fusion application and proceed to follow the

prompts for the VMware ESXi installer. Once finished, the VM will be installed and the VMware Fusion icon should appear in your Dock. You can launch it or leave it running in the background. Create a new Ubuntu VM If you have VMware Fusion, you can follow the steps to create a new VM. If not, it is possible to create an Ubuntu VM using the VMDK option from the VMware Fusion web site. JUnit is an open source framework that was written in Java that is designed to make it easy to write automated tests for Java. It is designed to be used together with another framework, such as JUnit4. JUnit was first released in 2001 and is currently maintained by a core team of four developers that are working full-time on it. JUnit includes many features such as:

- * Test categories.
- * Reusable test groups.
- * The ability to specify a rules for test names.
- * Test events.
- * A restricted set of types of exceptions thrown by the test engine.
- * Integration with the various tools that support it.
- * Ability to run tests based on their results.

JUnit vs MUnit The main difference between JUnit and MUnit is that JUnit is an open source project, whereas MUnit is proprietary. You can see more on the differences between JUnit and MUnit in JUnit 4 Documentation. Why JUnit? The choice to use JUnit to run test cases was based on the fact that it had a simple API, which is its most important feature. There are also multiple frameworks in the JUnit ecosystem that provide the following additional features:

- * Test suite code generators that allow you to define templates for test

First, why create another functionality is not necessary if there is no need to do it. Second, why make a project for it, when there are so many other ways to do it. Of course, there is something to do. I let you determine what that is. There are many reasons to have a stop-gap solution, such as the realization that you are wrong, or an obsession to get it working, or you are not properly supported by your team, or because the user would not know how to do it. If there is a dependency on a specific framework, even the most generic solution will require use of it, or some dependency on a framework (such as Spring). If you are required to use this approach, and you don't want to spend time on creating a new project (which you may not ever have to create, even if you have a requirement for it), then you can use the following. It should be noted that it is not recommended to use these solutions, but if needed, they will work. VS Code Install this extension This is very simple to install, and just needs to go into the extensions Manager. Once installed, it can be started by clicking on the icon. If no errors are encountered, then it is probably installed correctly. Starting the code The easiest way to start a new test is to do the following. After you have created your project, then you want to start it. Creating the test New file -> Project -> New Code -> Java Class Enter the class name By default, the project will be created in the same folder as the class, but there are a few things you can configure.
